The Formation of Coal. Carbon is the principal element in the composition of coal. A good specimen of hard dry anthracite would show from 91 to 98 per cent of carbon. The average anthracite of commerce, known technically as semi-anthracite, would show from 85 to 90 per cent, and the bituminous and semi-bituminous varieties would range all the way from 50 to 85 per cent. The amount of volatile matter contained increases from three per cent in the anthracites to 38 per cent in the bituminous species. The conduct of these different kinds of coal in combustion gives practical emphasis to the difference in composition. The anthracites burn with a small blue flame of carbonic oxide until thoroughly ignited, give off no smoke, and leave a comparatively small percentage of ashes. The

bituminous classes, on the other hand,

burn with a continuous yellowish

flame, give off considerable smoke, and

leave a large percentage of ashes. That coal is a vegetable product may be specifically proved. Indeed, ocular demonstration may be had of that fact. For while to the naked eye the structure of a fragment of mineral coal is purely amorphous, yet if that fragment be make so thin that it will transmit light, and 'if it be then examined through a powerful microscope its vegetable structure will be readily distinguished. Heat, pressure and confinement have produced the transformation. It is simply a process of smothered combustion. The operation may be watched in any peat bog. A peat bed is simply an accumulation of the remains of plants which have grown and decayed, and have been year by year buried more deeply under succeeding growths. Remove the upper layer, and you find peat with its 52 to 66 per cent of carbon. The deeper you go, that is, the older and longer buried the product, the better will be its quality for fuel. If this process of deposition should continue

through many geologic ages, the result would doubtless be true coal. It is known that during the carboniferous age the area now covered by the Middle, Southern and Western States was little more than a vast marsh burdened with the most luxu-THE public looks upon the adver- all favorable for the rapid and enormous growth of plants. The soil was rich and moist. The heat was greater than exists to-day at the torrid zone. The humidity of the atmosphere was great and constant. The air was laden with carbon. Plants luxuriated in it. They grew to enormous sizes. Plants which in our day are mere stems, a fraction of an inch in diameter, were in that time represented by trees from one to three feet in diameter and from 40 to 100 feet in height. This mass of vegetation, including more than 500 different species, was constantly growing, falling and decaying, each

succeeding growth forming a still richer bed for the vegetation to follow. If the theory propounded by Laplace is correct, our earth was at one time a ball of liquid fire. Cooling and condensation progressed from the surface toward the center. Contraction of the earth's crust necessarily followed, and vast areas of land sank and were covered by the waters. This process was still going on during the carboniferous age. The submergence of a bed of this incipient coal meant the cessation, for a time, of vegetable growth from its surface. That surface was covered instead by the sand, mud and gravel washed over it by the waves, by the drift from higher levels, and by the limestone deposits swept up to it from the sea. When contraction ceased for a time and the earth's crust again became stable, the waters began to recede, leaving behind them great wastes of mud and sand. And, following this slow recession to the sea, vegetation crept once more over the surface of the land, the soil grew rich with the products of decay, and plant life reigned and rioted anew. But cooling and contraction of the ter, thick or shallow, being covered in

turn by its layers of sand and salt. In this submergence and burial of the deposits of the coal era we find all the conditions necessary for the transformation of vegetable matter into coal. Only from one-ninth to oneixteenth of the mass of vegetable natter subjected to this heat and pressure was retained in the form of coal. This was largely carbon, the hydrogen and oxygen having been expelled. As we have already seen, the anthracite coal contains a much larger percentage of carbon than does the ituminous; and a much less quantity of volatile matter. Of the immense coal areas in the United States only an extremely small percentage are of the anthracite variety, and these all lie in the state of Pennsylvania, east of the Allegheny Mountains, with the exception of a small field in Rhode Island. It is not thought that the vegetable life which entered into one class differed in any material respect from that which entered into the

The presumption is natural, if not conclusive, that prior to the close of the carboniferous age all the coal deposits had been bituminous in character, but that the violent moveof the Appalachian revolution, the enormous pressure and intense heat. were sufficient to expel a large portion of the volatile matter from the bituminous coal beds, and otherwise change mediately overlying each coal seam, it is common to find the impressions of twigs, nuts, seeds, leaves, the most delicate fern tracery, and the tracery, and the trunks of great trees mashed flat between the layers, while in the softer beds of cannel coal, whole trees have been found, roots, trunks, branches, leaves, seeds, and all transformed into like material with that by which they were surrounded. One of the results of the violent disturbances of the earth's crust already noted was to leave great rents in it across the lines of strata. These rents are known geologically as fissures. They have faces which are either parallel or inclose a wedge shaped cavity. Some times igneous rock from the molten mass below was forced up into these openings; sometimes the cavities were filled with drift and rock fragments from the surface. In either case the mass became hard and compact, but with a character materially different from the rock on either side, the

formation of which was contemparaneous with that of the coal. The mind must exert itself to the utmost in order fully to realize through what vast periods of time the processes were continued by which the coal of to-day was formed. Still more lifficult of comprehension is the fact of the enormous amount of vegetable natter which entered into the composition of these beds of coal. In the Pottsville regions in Pennsylvania the average thickness of the combined anthracite coal seams is 120 feet. In order to make up this quantity of resultant coal, there must have been an average thickness of vegetable de-

posit amounting to at least 1,200 feet.

"That's whar I made In one of the selections there occurred n one of the selections there occurred a long and showy soprano solo, in cheap imitation of the Italian style. The young woman who attempted it sang gayly on till the clergyman evidently thought she had enjoyed her fair share of attention and glory. Accordingly he raised his hand as a signal, and the music ceased.

"Let that young woman with the red feather have done singing, and let Mary Ann Quilty sing the rest. It is Mary Ann's turn now."

Dies in His Fiance's Arms.

CINCINNATI, Ohio, December 2 .-Charles Wheeler, defaulting cashier of the Cincinnati Abbattoir Company fixed up, and it cost me 50 cents a who disappeared from here Saturday, week right along to have the dye put committed suicide to-day at Erlanger, Ky., under sensational circumstances. Wheeler managed to evade the officers for some time, although Erlanger is a suburb of this city. While in Erlanger he met and made love to Miss Anna Fisher and became secretly engaged to her. Afterward it was discovered he was a defaulter and had a wife living in Cincinnati. Wheeler then disappeared. Yesterday he returned to Erlanger and to-day Detective White, of this city located him at the home of Miss Fisher. At sight of the detective Wheeler drew a revolwhite, and was tickled to death about ver and attempted to shoot himself, but Miss Fisher threw her arms around his neck and prevented his firing for a time, but after a short struggle Wheeler succeeded in getting the weapon to his head and fired, falling with the girl still clinging to him. He expired instantly. Wheeler comes of aristocratic family and was a thorough scholar, having been educated for the

What Young Men Should Learn.

Here is a story from the Philadel phia Times that sounds very much like Robert J. Burdette, although that is only a guess:

"Remember, son, that the world is older than you are by several years that for thousands of years it has been so full of smarter, better and younger men than yourself that their feet stuck light of your wisdom abroad, but don't dazzle people with it. And don't imagine a thing is so, simply because you say it is so. Don't be too sorry the bank in five minutes than, perhaps, your handsome autograph can do during the balance of your mortal life. Young men are useful and they are also ornamental, and we all like them

out of the dormer windows, but when they died the old globe went jogging along, and not one person in ten millions went to the funeral, or even heard of their death. Be as smart as you can, of course. Know as much as you can without blowing the packing out of your cylinder heads. Shed the for your father because he knows so much less than you do. The world has great need of young men, but no greater need than the young men have of it. Your clothes fit you better than your father's fit him-they cost more money; they are more stylish; your mustache is neater, the cut of your hair is better and you are prettier, oh, for prettier than 'pa.' stop a moment, young man and reflect. The old gentleman gets the bigger salary and his homely, scrambling signature on the business end of a check will drain more money out of

-but they are no novelties, son-oh
